

Everything the platform does

A complete inventory of delivered capability, phase 1 through phase 5.

7 September 2026

Compiled

Phases 1–5

Scope

307

Automated tests

24

Database migrations

Velocity Business OS is a multi-tenant platform covering the whole client lifecycle — from first contact to renewal — for a services business. This document lists what has been built. A companion delivery report covers status, verification and what remains outstanding.

TESTS

PHASE 1

The client lifecycle

DELIVERED

Sales pipeline

Lead → Qualification → Discovery → Diagnosis → Solution → Proposal → Negotiation → Won

A guarded state machine. A deal cannot skip a stage or move without meeting that stage's requirements, and the rule is enforced in the database — not merely in the interface.

Qualification checklist, discovery capture and diagnosis

Structured records rather than free text, so the reason a deal advanced is legible afterwards.

Kanban board with drag-to-transition

Dragging a card attempts a transition and reports why it was refused, rather than silently reverting.

Solution design and service catalogue

Reusable services with rates and estimates, composed into a priced solution.

Proposals

Versioned proposals with an approval trail

Draft → internal review → approved → sent → accepted. An accepted version is frozen and can never be edited.

Separate authority to approve and to send

The person who approves a proposal is not automatically the person who may send it.

Legal and contracts

Deterministic contract generation from templates

Rendering *fails* on a missing variable rather than producing a document with a blank in it. Every rendered document records the exact values used.

NDA, MSA, SOW, addendum and amendment types

With parent–child relationships, so an amendment always knows what it amends.

E-signature integration

Zoho Sign, plus a fully functional manual provider so the complete legal workflow runs without a provider account.

Executed-document capture with SHA-256 verification

The signed document is stored and hashed. A file whose bytes no longer match its recorded hash is quarantined and cannot be downloaded.

The legal gate

A client cannot be onboarded until the required agreements are executed and the required payments met. Enforced by a database function, so no code path can bypass it. Overrides are possible, permanent and recorded.

Finance

Payment requirements, invoices and payments

Advance, milestone, final and full requirements, any of which can block onboarding.

Exact decimal money and multi-currency

Money is never a floating-point number. Conversion uses recorded FX rates and returns nothing rather than assuming parity when a rate is missing.

Delivery

Onboarding checklists, projects, workstreams, tasks and deliverables

Provisioned automatically when a deal is won and the legal gate is satisfied.

KPIs with baselines, targets and measurements

Per client and per project, with client-visible flags.

Project health tracking and client reports

Platform foundations

Multi-tenant isolation enforced by the database

Row-level security is enabled *and forced* on every tenant table, deny-by-default. One customer cannot read another's data even if application code asks for it.

Role-based access control with ownership scopes

133 permissions across 8 roles, each expressible as own / team / organisation.

Complete audit trail and a domain event log

Every consequential action is recorded with who, when, and from which request.

Document management with versioning and immutability

Confidential documents require a separate permission; a denied attempt is itself recorded.

Background worker with retry and backoff

AI assistant

Answers questions about your own data

Eight fixed read-only tools. No generated SQL. Restricted to what the person asking is permitted to see.

The model can never write to a record

Anything it drafts becomes a proposal that a person reviews, edits and approves before it takes effect. Enforced by a database trigger, not by convention.

Every answer shows its sources

The list of tool calls that produced an answer is shown alongside it, so the working can be checked.

Automation engine

WHEN → IF → THEN rules over domain events

A closed set of eleven actions. There is deliberately no “send email” action anywhere in the product.

Loop protection

Chain depth and per-record cooldown, both recorded on every run.

PHASE 2 Production readiness

DELIVERED

Amazon SES email provider NEW

Full implementation. A rejected sender identity is reported as a configuration fault rather than a temporary one, so the queue stops instead of retrying a broken setup indefinitely.

Browser test suite NEW

29 tests that drive the real application in a real browser. They verify that every page not only renders but *responds to a click* — a distinction that matters, because a page whose JavaScript failed looks completely normal and does nothing.

Preflight diagnostic (`npm run doctor`) NEW

Checks the database, migrations, seed data, security posture, storage credentials and the AI key against the live services, and reports the actual reason for each failure.

Performance work NEW

Sign-in identity resolution reduced from five database queries to one; transaction setup from five network round trips to two; rate limiting from four to one. Page response improved from roughly 3.9 seconds to under 0.4.

Runtime version pinned

A deployment on an unsupported Node version now fails loudly rather than warning quietly.

PHASE 3 Client portal

DELIVERED

A separate application for your clients

Six screens: overview, projects, project detail, documents, invoices and reports. Clients see their own work as their delivery team sees it.

Clients can accept or reject deliverables

A rejection must say why. The decision is attributed to the individual, and appears on both timelines.

Per-person permissions

Three independent switches — documents, invoices, approve deliverables — set per person from the client record.

Documents delivered by short-lived signed links

Issued per click and expiring in fifteen minutes, so a link cannot outlive the page it was meant for. Confidential documents are never visible to a client.

Invite and revoke access, with a full record

Clients set their own password from a one-time link; no password is ever generated for them. Revoked access is retained, not deleted — “who could see our invoices, and until when” is a question that gets asked after the fact.

How the boundary is built

The portal reads through 15 dedicated database projections that *physically exclude* cost, margin, internal notes and AI analysis. Those columns are not hidden or filtered — they do not exist in what the portal can query, so no future mistake in the application can expose them. Portal users hold no internal membership, so every internal security policy denies them by construction.

PHASE 4 Revenue retention

DELIVERED

Renewal engine

Every executed contract with an end date opens a renewal cycle as it approaches its notice window. Each cycle has an owner, a decision and an outcome — renewed, lost, auto-renewed or not renewing.

A lost renewal must record why

The single most useful field in the system. Reasons are counted on the renewals dashboard, so churn becomes something you can act on rather than only observe.

Retention rate and value at risk

Value due in the next 90 days, value currently being worked, and twelve-month retention as a share of value that actually reached a decision.

Pipeline forecast

Weighted value by expected close month, shown beside unweighted open value and already-committed value — because a single weighted figure invites more confidence than the method supports.

Delivery profitability

Invoiced revenue less recorded cost, per project, with hours used against estimate. Restricted to those permitted to see cost. A project with nothing invoiced reports “no data” rather than a misleading negative margin.

On the honesty of the numbers

Amounts that cannot be converted to your base currency — because no exchange rate has been loaded — are excluded from every total *and counted*, with the report saying so explicitly. A total that quietly absorbs an unconverted currency looks exactly like a correct one, which makes it worse than no total at all.

PHASE 5 Integrations

BUILT · UNVERIFIED

No-code automation builder

A visual WHEN → IF → THEN editor. Create, edit, activate, pause and delete rules without a developer. Switching a rule on is a separate action from editing it, and the two are recorded separately.

Slack notifications

Alerts posted to a channel. Every message is recorded before it is attempted, so one lost to an outage leaves a trace rather than disappearing.

WhatsApp notifications

Via the Meta Cloud API, using an approved message template. The system *refuses* to send without one rather than attempting it, because a non-template message outside the 24-hour window is accepted by the API and never delivered — a failure that looks identical to success.

Gmail and Microsoft 365 mailbox sync

Client email appears on the client's timeline automatically. Read-only access is requested; the system asks for no permission to send, modify or delete.

Three rules that hold by construction

- **Incoming email is data, never an instruction.** No automation can be triggered by it, and the AI assistant reads it through the same restricted tools as everything else.
- **Nothing is ever auto-replied.** There is no path from a received message to a sent one that does not pass through a person.
- **Only mail exchanged with a known contact is stored.** A mailbox belongs to an individual and most of its contents are none of the platform's business.

Security posture, throughout

GUARANTEE	HOW IT IS ENFORCED
One customer cannot read another's data	Row-level security, forced on all 85 tables, deny-by-default
Lifecycle changes follow their rules	Database triggers reject any status change made outside the transition service
Onboarding cannot bypass legal or payment	A database function asserts the gate; overrides are permanent and recorded
The AI cannot change anything	Read-only tools; a trigger requires human approval before any drafted action executes
Automations cannot send email	The action is absent from the schema, not merely disabled
Clients cannot see cost or margin	Those columns do not exist in the portal's projections
Signed documents cannot be swapped	SHA-256 verification; a mismatch quarantines the document
Integration tokens cannot leak from a backup	Credentials are referenced by name and never written to the database
